# Data Structures Sorting

CS284

# **Objectives**

- ▶ To learn how to implement the following sorting algorithms:
  - selection sort
  - bubble sort
  - insertion sort
  - ► shell sort
  - ► merge sort
  - heapsort
  - quicksort
- ► To understand the differences in performance of these algorithms, and which to use for small, medium arrays, and large arrays

Shell Sort: A Better Insertion Sort

Merge Sort

Heapsort

#### Shell Sort: A Better Insertion Sort

- ▶ A type of insertion sort, but with  $\mathcal{O}(n^{3/2})$  or better performance than the  $\mathcal{O}(n^2)$  sorts
- ▶ It is named after its discoverer, Donald Shell
- ► Can be thought of as a divide-and-conquer approach to insertion sort
- Instead of sorting the entire array, sorts many smaller subarrays using insertion sort before sorting the entire array

# Algorithm - Array table of size n

```
gap = n/2
while (gap > 0) {

for each array element e from position gap to n-1 {
    Insert e where it belongs in its subarray.
}

if (gap is 2)
then gap = 1
else gap = gap/2.2 // chosen by experimentation
}
```

▶ We shall refine line 4 in the next slide

Tracing an example

# Refinement of Step 4, the Insertion Step

```
qap = n/2
   while (gap > 0) {
    for each array element e in array table from position gap to n-1 {
     nextPos is the position of e
4
     nextVal = table[e]
     while (nextPos>gap && table[nextPos-gap]>nextVal) {
6
       Shift the element at nextPos-qap to position nextPos
       nextPos = nextPost-qap
8
    Insert nextVal at nextPos
10
12
    if (gap is 2)
     then gap = 1
    else qap = qap/2.2 // chosen by experimentation
14
```

### Analysis of Shell Sort

- ▶ Because the behavior of insertion sort is closer to  $\mathcal{O}(n)$  than  $\mathcal{O}(n^2)$  when an array is nearly sorted, presorting speeds up later sorting
- ▶ This is critical when sorting large arrays where the  $\mathcal{O}(n^2)$  performance becomes significant
- General analysis is open research problem
  - Performance depends on selection of (decreasing) gap
  - Our algorithm initially sets gap to n/2 and then divides by 2.2 and truncates the result
  - ▶ Empirical studies show that this approach yields performance  $\mathcal{O}(^{5/4})$  or even  $\mathcal{O}(n^{7/6})$ , but there is no theoretical basis for the result

# Analysis of Shell Sort (cont.)

- ▶ If successive powers of 2 used for gap, performance is  $\mathcal{O}(n^2)$
- ▶ If successive values for gap are based on Hibbard's sequence,

$$2k-1$$
 (i.e. 31, 15, 7, 3, 1)

it can be proven that the performance is  $\mathcal{O}(n^{3/2})$ 

▶ Other sequences give similar or better performance

#### Code for Shell Sort

```
public class ShellSort {
     public static <T extends Comparable <T>> void sort(T[] table) {
         // Gap between adjacent elements.
3
         int gap = table.length / 2;
         while (gap > 0) {
5
          for (int nextPos = gap; nextPos<table.length; nextPos++)</pre>
             // Insert element at nextPos in its subarray.
7
             insert (table, nextPos, gap);
9
           // Reset gap for next pass.
           if (gap == 2)
11
             \{ qap = 1; \}
13
           else
             { gap = (int) (gap / 2.2); }
15
         } // End while.
```

#### Code for Shell Sort

Shell Sort: A Better Insertion Sort

Merge Sort

Heapsort

# Merge

- ► A merge is a common data processing operation performed on two sequences of data with the following characteristics
  - Both sequences contain items with a common compareTo method
  - The objects in both sequences are ordered in accordance with this compareTo method
- ► The result is a third sequence containing all the data from the first two sequences

# Merge Algorithm - leftSeq and rightSeq

```
Access the first item from both sequences.

while (not finished with either sequence) {
   Compare the current items from the two sequences

Copy the smaller current item to the output sequence, and access the next item from the input sequence whose item was copied.

Copy any remaining items from leftSeq to the output sequence.

Copy any remaining items from rightSeq to the output sequence.
```

# Trace of Merge Algorithm

0	1	2	3
30	50	60	90

0	1	2	3	4
15	20	33	45	80

# Trace of Merge Algorithm

0	1	2	3
30	50	60	90

0	1	2	3	4
15	20	33	45	80

0	1	2	3	4	5	6	7	8
15	20	30	33	45	50	60	80	90

# Analysis of Merge

- ► For two input sequences containing *n* and *m* elements resp., each element needs to move from its input sequence to the output sequence
- ▶ Merge time is  $\mathcal{O}(n+m)$

# Code for Merge

```
private static <T extends Comparable<T>> void merge(T[]
   outputSeq, T[] leftSeq, T[] rightSeq)
       int i = 0; // Index into the left input sequence.
       int j = 0; // Index into the right input sequence.
4
       int k = 0; // Index into the output sequence.
6
       while (i < leftSeq.length && j < rightSeq.length) {</pre>
8
        // Find smaller one insert into the output sequ.
        if (leftSeg[i].compareTo(rightSeg[i])<0){</pre>
             outputSeg[k++] = leftSeg[i++];
10
         } else
            { outputSeg[k++] = rightSeg[j++]; }
12
       // Copy remaining input from left seg. into output.
14
       while (i < leftSeq.length) {
            outputSea[k++] = leftSea[i++];
16
       // Copy remaining input from right seq. into output.
18
       while (j < rightSeq.length) {</pre>
            outputSeg[k++] = rightSeg[j++];
20
22
```

# Merge Sort

- We can modify merging to sort a single, unsorted array
  - 1. Split the array into two halves
  - 2. Sort the left half
  - 3. Sort the right half
  - 4. Merge the two
- This algorithm can be written with a recursive step

# (recursive) Algorithm for Merge Sort

```
if (tableSize>1) {
    halfsize = tableSize/2
    Allocate a table leftTable of size halfSize
4    Allocate a table rightTable of size tableSize-halfSize
    Copy elements from table[0..halfSize] to leftTable
6    Copy elements from table[halfSize+1..tableSize] to rightTable
    Recursively apply merge sort to leftTable
8    Recursively apply merge sort to rightTable
    Apply merge algorithm to leftTable and rightTable
10 }
```

#### ► Tracing an example

0	1	2	3	4	5	6	7	8
45	50	20	60	80	15	30	33	90

# Complexity of Merge Sort

- ▶ Merge sort time is  $\mathcal{O}(n \log n)$ 
  - ▶ *n* for the total time for merging, per level
- ▶ But it requires, temporarily, *n* extra storage locations

# Code for Merge Sort

```
public class MergeSort {
   public static <T extends Comparable <T>> void sort(T[] table) {
     // A table with one element is sorted already.
     if (table.length > 1) {
       // Split table into halves.
6
       int halfSize = table.length / 2;
       T[] leftTable = (T[]) new Comparable[halfSize];
       T[] rightTable = (T[])new Comparable[table.length-halfSize];
8
       System.arraycopy(table, 0, leftTable, 0, halfSize);
       System.arraycopy(table, halfSize, rightTable, 0,
10
                         table.length - halfSize);
              //Sort the halves.
12
       sort (leftTable);
       sort (right Table):
14
16
       // Merge the halves.
       merge(table, leftTable, rightTable);
18
```

Shell Sort: A Better Insertion Sort

Merge Sort

Heapsort

### Heapsort

- Heapsort has the same complexity as Mergesort
- In contrast to Mergesort, Heapsort does not require any additional storage
- As its name implies, heapsort uses a heap to store the array
  - When used as a priority queue, a heap maintains a smallest value at the top
  - ▶ Naive heapsort:
    - place an array's data into a heap,
    - then remove each heap item and move it back into the array

### Naive Version of a Heapsort Algorithm

▶ This version of the algorithm requires *n* extra storage locations

```
Insert each value from table into a priority queue (heap).
i=0

while (priority queue is not empty) {
    Remove next item from the queue
    Insert it back into the array at position i
    i++

}
```

#### ► Tracing an example

0					5		7
15	20	30	45	50	60	80	90

### Revising the Heapsort Algorithm

- We can do better in terms of space usage
- ► In heaps we've used so far, each parent node value was not greater than the values of its children (minHeap)
- We can build a heap so that each parent node value is not less than its children (maxHeap)
- ► Then,
  - move the top item to the bottom of the heap
  - reheap, ignoring the item moved to the bottom
- If we implement the heap as an array,
  - each element removed will be placed at end of the array, and
  - the heap part of the array decreases by one element

# Algorithm for In-Place Heapsort

```
1 Build a maxHeap h by rearranging the elements in table
   while (h is not empty) {
3     Remove the first item h by swapping it with the last item in h
     Restore the heap property on h
5 }
```

#### ► Tracing an example

0	1	2	3	4	5	6	7	8	9	10	11	12
74	66	89	6	39	29	76	32	18	28	37	26	20

# Analysis of Heapsort

- ▶ Because a heap is a complete binary tree, it has log *n* levels
- ▶ Building a heap of size *n* requires finding the correct location for an item in a heap with log *n* levels
- ▶ Each insert (or remove) is  $\mathcal{O}(\log n)$
- ▶ With *n* items, building a heap is  $O(n \log n)$
- No extra storage is needed

```
public class HeapSort
    public static <T extends Comparable <T>> void sort(T[] table)
3
      buildHeap(table): // build maxHeap
      shrinkHeap(table); // transform heap into a sorted array.
5
    private static <T extends Comparable <T>> void buildHeap(T[] table) {
7
      int n = 1:
9
      while (n < table.length) {</pre>
        n++; // Add a new item to the heap and reheap.
11
        int child = n - 1;
        int parent = (child - 1) / 2; // Find parent.
13
        while (parent >= 0
            && table[parent].compareTo(table[child]) < 0) {
15
          swap(table, parent, child);
          child = parent;
17
          parent = (child - 1) / 2;
19
```

```
private static <T extends Comparable <T>> void shrinkHeap(T[] table) {
2
     int n = table.length;
     // Invariant: table[0...n - 1] forms a heap.
4
     // table[n...table.length - 1] is sorted.
     while (n > 0) {
6
       n--;
       swap(table, 0, n);
8
       // table[1...n - 1] form a heap.
       // table[n...table.length - 1] is sorted.
10
       int parent = 0;
       while (true) {
12
         int leftChild = 2 * parent + 1;
         if (leftChild >= n)
14
           break; // No more children.
16
       // continued
18
```

```
int rightChild = leftChild + 1;
       // Find the larger of the two children.
2
       int maxChild = leftChild;
       if (rightChild<n // There is a right child.
          && table[leftChild].compareTo(table[rightChild])<0) {
         maxChild = rightChild:
6
8
       // If the parent is smaller than the larger child,
       if (table[parent].compareTo(table[maxChild]) < 0) {</pre>
10
          // Swap the parent and child.
          swap(table, parent, maxChild);
12
         // Continue at the child level.
14
         parent = maxChild;
16
       else { // Heap property is restored.
         break: // Exit the loop.
18
20
```

```
/** Swap the items in table[i] and table[j].
         Oparam table The array that contains the items
2
         @param i The index of one item
         @param j The index of the other item
4
      */
      private static <T extends Comparable <T>>
6
         void swap(T[] table, int i, int j) {
        T temp = table[i];
8
        table[i] = table[j];
        table[j] = temp;
10
12
```
